# Create X_train, X_test, y_train, y_test
from sklearn.model_selection import train_test_split
# from library.module import class

X_train, X_test, y_train, y_test = train_test_split(X,
                                                    y,
                                                    # Controls the shuffling and
                                                    # Pass an int for reproducibility
                                                    random_state=1,
                                                    # If not None, data is split
                                                    # https://www.scribbr.com/
                                                    stratify=y)
```

Data Pre-Processing

Scale the training and testing data using the `StandardScaler` from `sklearn`. Remember that when scaling the data, you only scale the features data (`X_train` and `X_testing`).

In [9]:

```
# Create the StandardScaler instance to normalize the values individually, because
# some columns have many more values than others
from sklearn.preprocessing import StandardScaler
scaler = StandardScaler()
new_X_train=pd.get_dummies(X_train, columns=["homeowner"])
new_X_test=pd.get_dummies(X_test, columns=["homeowner"])
scaler.fit(new_X_train)
print(f'the scaler mean is {scaler.mean_}' )
```

```
the scaler mean is [9.80612533e+03 7.29255941e+00 4.92239476e+04 3.77350994e-01
3.82654079e+00 3.92351080e-01 1.92239476e+04 4.96354382e-01
```

```
4.01241574e-01 1.02404045e-011
```

```
In [10]: # Fit the Standard Scaler with the training data  
# When fitting scaling functions, only train on the training dataset  
data_scaler = StandardScaler()  
  
data_scaler.fit(new_X_train)
```

```
Out[10]: StandardScaler()
```

```
In [11]: # Scale the training and testing data  
X_train_scaled = data_scaler.transform(new_X_train)  
X_test_scaled = data_scaler.transform(new_X_test)
```

Simple Logistic Regression

```
In [12]: from sklearn.linear_model import LogisticRegression  
model = LogisticRegression(solver='lbfgs', random_state=1)  
model.fit(X_train_scaled, y_train)
```

```
Out[12]: LogisticRegression(random_state=1)
```

```
In [13]: # Calculated the balanced accuracy score  
from sklearn.metrics import balanced_accuracy_score  
y_pred = model.predict(X_test_scaled)  
balanced_accuracy_score(y_test, y_pred)
```

```
Out[13]: 0.9892813049736127
```

```
In [14]: # Display the confusion matrix  
from sklearn.metrics import confusion_matrix  
confusion_matrix(y_test, y_pred)
```

```
Out[14]: array([[ 615,    10],  
                 [ 102, 18657]], dtype=int64)
```

```
In [15]: # Print the imbalanced classification report  
from imblearn.metrics import classification_report_imbalanced  
print(classification_report_imbalanced(y_test, y_pred))
```

Oversampling

In this section, you will compare two oversampling algorithms to determine which algorithm results in the best performance. You will oversample the data using the naive random oversampling algorithm and the SMOTE algorithm. For each algorithm, be sure to complete the following steps:

1. View the count of the target classes using `Counter` from the collections library.
2. Use the resampled data to train a logistic regression model.
3. Calculate the balanced accuracy score from `sklearn.metrics`.
4. Print the confusion matrix from `sklearn.metrics`.
5. Generate a classification report using the `imbalanced_classification_report` from `imbalanced-learn`.

Note: Use a random state of 1 for each sampling algorithm to ensure consistency between tests.

Naive Random Oversampling

In [16]:

```
# Resample the training data with the RandomOversampler
from imblearn.over_sampling import RandomOverSampler

ros = RandomOverSampler(random_state=1)
X_resampled, y_resampled = ros.fit_resample(X_train_scaled, y_train)

# View the count of target classes with Counter
print(Counter(y_resampled))

Counter({'low_risk': 56277, 'high_risk': 56277})
```

In [17]:

```
# Train the Logistic Regression model using the resampled data
from sklearn.linear_model import LogisticRegression
```

In [18]:

```
# Calculated the balanced accuracy score
model = LogisticRegression(solver='lbfgs', random_state=1)
print(model.fit(X_resampled, y_resampled))

LogisticRegression(random_state=1)
```

In [19]:

```
# Display the confusion matrix
from sklearn.metrics import confusion_matrix

y_pred = model.predict(X_test_scaled)
```

In [20]:

```
# Print the imbalanced classification report
print(confusion_matrix(y_test, y_pred))
```

```
[[ 622     3]
 [ 111 18648]]
```

SMOTE Oversampling

In [21]:

```
# Resample the training data with SMOTE
from imblearn.over_sampling import SMOTE
from collections import Counter
X_resampled, y_resampled = SMOTE(random_state=1, sampling_strategy=1.0).fit_resample(X_train, y_train)
# View the count of target classes with Counter
print(Counter(y_resampled))
```

```
Counter({'low_risk': 56277, 'high_risk': 56277})
```

In [22]:

```
# Train the Logistic Regression model using the resampled data
from sklearn.linear_model import LogisticRegression
```

In [23]:

```
# Calculated the balanced accuracy score
model = LogisticRegression(solver='lbfgs', random_state=1)
print(model.fit(X_resampled, y_resampled))
```

```
LogisticRegression(random_state=1)
```

In [24]:

```
# Display the confusion matrix
y_pred = model.predict(X_test_scaled)
confusion_matrix(y_test, y_pred)
```

Out[24]:

```
array([[ 622,      3],
       [ 110, 18649]], dtype=int64)
```

In [25]:

```
# Print the imbalanced classification report
print(confusion_matrix(y_test, y_pred))
```

```
[[ 622     3]
 [ 110 18649]]
```

Undersampling

In this section, you will test an undersampling algorithm to determine which algorithm results in the best performance compared to the oversampling algorithms above. You will undersample the data using the Cluster Centroids algorithm and complete the following steps:

1. View the count of the target classes using `Counter` from the `collections` library.
2. Use the resampled data to train a logistic regression model.
3. Calculate the balanced accuracy score from `sklearn.metrics`.
4. Display the confusion matrix from `sklearn.metrics`.
5. Generate a classification report using the `imbalanced_classification_report` from `imbalanced-learn`.

Note: Use a random state of 1 for each sampling algorithm to ensure consistency between tests

In [26]:

```
# Resample the data using the ClusterCentroids resampler
from imblearn.under_sampling import ClusterCentroids

cc = ClusterCentroids(random_state=1)
X_resampled, y_resampled = cc.fit_resample(X_train_scaled, y_train)

# View the count of target classes with Counter
Counter(y_resampled)
```

Out[26]: Counter({'high_risk': 1875, 'low_risk': 1875})

In [27]:

```
# Train the Logistic Regression model using the resampled data
from sklearn.linear_model import LogisticRegression
model = LogisticRegression(solver='lbfgs', random_state=1)
model.fit(X_resampled, y_resampled)
```

Out[27]: LogisticRegression(random_state=1)

In [28]:

```
# Calculate the balanced accuracy score
from sklearn.metrics import balanced_accuracy_score

balanced_accuracy_score(y_test, y_pred)
```

Out[28]: 0.9946680739911509

In [30]:

```
# Display the confusion matrix
from sklearn.metrics import confusion_matrix
y_pred = model.predict(X_test_scaled)
confusion_matrix(y_test, y_pred)
```

Out[30]: array([[620, 5],
 [102, 18657]], dtype=int64)

In [31]:

```
# Print the imbalanced classification report
from imblearn.metrics import classification_report_imbalanced
print(classification_report_imbalanced(y_test, y_pred))
```

sup	pre	rec	spe	f1	geo	iba
high_risk	0.86	0.99	0.99	0.92	0.99	0.99
625						
low_risk	1.00	0.99	0.99	1.00	0.99	0.99
8759						1
avg / total	1.00	0.99	0.99	0.99	0.99	0.99
9384						1

Combination (Over and Under) Sampling

In this section, you will test a combination over- and under-sampling algorithm to determine if

the algorithm results in the best performance compared to the other sampling algorithms above. You will resample the data using the SMOTEENN algorithm and complete the following steps:

1. View the count of the target classes using `Counter` from the collections library.
2. Use the resampled data to train a logistic regression model.
3. Calculate the balanced accuracy score from `sklearn.metrics`.
4. Display the confusion matrix from `sklearn.metrics`.
5. Generate a classification report using the `imbalanced_classification_report` from `imbalanced-learn`.

Note: Use a random state of 1 for each sampling algorithm to ensure consistency between tests

In [32]:

```
# Resample the training data with SMOTEENN
from imblearn.combine import SMOTEENN

sm = SMOTEENN(random_state=1)
X_resampled, y_resampled = sm.fit_resample(X_train_scaled, y_train)

# View the count of target classes with Counter
print(Counter(y_resampled))

Counter({'low_risk': 55885, 'high_risk': 55652})
```

In [33]:

```
# Train the Logistic Regression model using the resampled data
model = LogisticRegression(solver='lbfgs', random_state=1)
model.fit(X_resampled, y_resampled)
```

Out[33]: `LogisticRegression(random_state=1)`

In [34]:

```
# Calculate the balanced accuracy score
from sklearn.metrics import balanced_accuracy_score

balanced_accuracy_score(y_test, y_pred)
```

Out[34]: 0.9932813049736127

In [35]:

```
# Display the confusion matrix
y_pred = model.predict(X_test_scaled)
confusion_matrix(y_test, y_pred)
```

Out[35]: `array([[622, 3],
 [110, 18649]], dtype=int64)`

In [36]:

```
# Print the imbalanced classification report
from imblearn.metrics import classification_report_imbalanced

print(classification_report_imbalanced(y_test, y_pred))
```

	pre	rec	spe	f1	geo	iba
sup						

high_risk	0.85	1.00	0.99	0.92	0.99	0.99	
625							
low_risk	1.00	0.99	1.00	1.00	0.99	0.99	1
